TITLE: Method of making pathogen-resistant plants by transformation with a fatty acid desaturase
gene
DATE-ISSUED: May 1, 2001

US-CL-CURRENT: 800/279

APPL-NO: 9/ 143567
DATE FILED: August 28, 1998

PARENT-CASE:
This application claims priority to U.S. Provisional Application No. 60/057,510, filed Sep. 4,
1997, which is incorporated by reference herein.

IN: Chin; Chee-Kok, Wang; Chunlin, Xing; Jinsong

AB: The present invention provides pathogen-resistant transgenic plants and methods
of making the plants. The transgenic plants display enhanced resistance to a variety of
fungal, bacterial and viral plant pathogens due to expression of a gene that increases the
unsaturated fatty acid content of the plant's cells, as compared with an equivalent, but
non-transformed plant. The preferred embodiment of the invention is a plant expressing a
heterologous .DELTA.-9 desaturase gene from yeast, which particularly increases cytosolic
quantities of 16:1, 16:2 and 18:1 fatty acids.

AB: The invention relates to novel plant plasmid vectors comprising geminivirus DNA
or a portion thereof having inserted therein a heterologous DNA sequence or gene, to
processes and DNA intermediates useful in producing said vectors and to methods utilizing
such vectors to replicate and express heterologous DNA sequences or genes in plants. In some
embodiments, methods and compositions are provided for Ti plasmid delivery of these novel
vectors into plants. In other embodiments, methods and compositions are provided which allow
for the generation of geminivirus DNA containing plant plasmids in stably transformed
plants. In still other embodiments, methods and compositions are provided for replicating
and expressing heterologous DNA sequences or genes in plants employing the geminivirus DNA
containing vectors of the present invention without causing disease symptoms.

TITLE: Plant vectors

DEPR:
While neither the transgenic A- or B-containing plants exhibited virus disease symptoms, it was
demonstrated, in Example 14, supra, that inoculation of B-containing plants with vectors
comprising the TGMV A-component subsequently displayed virus symptoms. Subsequent experiments by
Sunter et al (1987) have shown that one-quarter of the progeny produced by crossing a transgenic
A plant with a transgenic B plant show geminivirus symptoms and contain infectious virus
particles. These results show that the integrated tandem copies of the TGMV DNA's are functional,
are able to be released from their integrated state and maintain their ability to produce
infectious virus when genetically combined in the same cell. These results further demonstrate
that the A component contains the necessary sequences and/or genes to

enable release of B
component DNA from its integrated state. Specifically, the ability of TGMV-A component DNA (e.g.
coat protein-encoding geminivirus DNA molecules) to cause the release and subsequent replication
of TGMV-B component DNA molecules, demonstrates that a geminivirus trans-acting factor(s) is
(are) encoded in the TGMV-A component DNA. Additionally, these results demonstrate that both the
TGMV-A and -B component DNA's contain a sequence or sequences responsive to the geminivirus
trans-acting factor(s). A geminivirus DNA sequence responsive to a geminivirus trans-acting
factor is understood herein to mean a geminivirus DNA sequence, the presence of which coupled to
the presence of a geminivirus trans-acting factor, results in the autonomous replication of a DNA
molecule containing the responsive sequence. it was further demonstrated, in Examples 13 and 14
supra, that heterologous DNA sequences can be inserted into and/or in place of the coat protein
gene without disrupting the ability of the TGMV A-component to form plasmid DNA molecules in
plant cells or cause disease symptoms in transgenic plants containing tandem copies of the TGMV
B-component. These results demonstrate that the DNA sequences coding for the geminivirus coat
protein per se are not required for replication of geminivirus DNA or geminivirus-containing
plasmid DNA molecules in plants and/or plant cells. Specifically, Examples 13 and 14, supra,
teach that neither the geminivirus trans-acting factor nor sequences responsive to said factor
are contained within the DNA sequences encoding the TGMV coat protein. These foregoing examples
further set forth a method by which one of skill in the art can determine the minimal sequence or
sequences required for binary geminivirus replication in a plant cell. Specifically, the
foregoing examples demonstrate that by performing conventional deletion and/or mutation analysis,
a minimal binary geminivirus replicon can be determined.

BSPR:
PAP displays broad-spectrum antiviral activity against plant viruses, herpes simplex virus,
cytomegalovirus, poliovirus, and influenza virus. Aron et al., Agents Chemotherapy, 17, 1032
(1980). In fact, pokeweed antiviral protein was discovered due to its ability to inhibit the
transmission of tobacco mosaic virus (TMV) in plants and it was subsequently demonstrated that
the purified protein was equally effective against a number of other plant viruses. Tomlinson et
al., J. Gen. Virol., 22, 225 (1974). All of these experiments were performed in a similar manner;
PAP was mixed with the virus inoculum which was then rubbed on plant leaves in the presence of an
abrasive substance, such as carborundum, which damages the tissue allowing the entry of the virus
and presumably the PAP. Using this method, it was found that highly diluted solutions of PAP were
capable of inhibiting local lesion formation caused by southern bean mosaic virus as well as
cucumber mosaic virus. Wyatt et al., Phytopath., 59, 1787 (1969); Tomlinson et al., cited supra.
Using the local lesion assay system on Phaseolus vulgaris, it has been shown that PAP inhibited
viral infection at very low concentrations. Irvin et al., Arch. Biochem. Biophys., 200, 418
(1980). PAP has also been shown to effectively inhibit TWV infection of tobacco protoplasts with
nearly complete inhibition obtained with 10 .mu.g/mL (.apprxeq.300 nM). Grasso et al.,
Phytopath., 98, 53 (1980). Furthermore, in a study done to compare the relative antiviral
properties of a number of ribosome inactivating proteins (RIPs) including PAP upon the formation
of local lesions on Nicotiana glutinosa by TMV, it was found that all of the RIPs tested had
antiviral activity, but none of the studied RIP's were as effective as PAP. Stevens et al.,
Experientia, 37, 257 (1981).

Oct 17, 2000

DOCUMENT-IDENTIFIER: US 6133505 A
TITLE: Phytopathogenic geminivirus resistant transgenic plants and seeds and methods for
obtaining same by introduction of mutated C1 gene

DEPR:
To confirm these results, leaf discs of potentially resistant plants are agroinoculated with the
STYLCV. Seven days after agroinoculation, the various forms of viral DNA (ss and ds) are detected
in the leaf discs of non-transgenic N. benthamiana. This provides evidence of good infectivity of
the clone used for inoculating the leaf discs. Three plants display very reduced replication
relative to a positive control: these are resistant plants (absence of symptoms, but residual
replication of the viral DNA). Two plants do not have any form of viral DNA: these are completely
resistant plants. Curiously, two plants have the various forms of viral DNA, whereas no signal
was visible in squash or in Southern blot. This might be explained by the "inoculum pressure"
used in the experiments of agroinoculation of leaf discs. This "inoculum pressure" is higher than
was used in the agroinoculation of whole plants, and so would lead to a change of the ratio of
mutated to wild-type C1 proteins in favour of the wild-type protein, and consequently to
replication of the viral DNA. On the other hand this (ambiguous) behaviour might correspond to an
inhibition of the movement (at long range?) of the virus in planta, since the agroinoculation of
leaf discs makes it possible to avoid phenomena of movement at long range.

AB: The invention relates to assembled particles of a plant virus containing a
predetermined foreign peptide as part of the coat protein of the virus, and a method for
their production. The foreign peptide is preferably a biologically functional peptide, the
biological application of which requires or is enhanced by presentation of the peptide in
association with a larger molecule or particle.

L9: Entry 5 of 52
File: USPT
Aug 29, 2000

DOCUMENT-IDENTIFIER: US 6110466 A
TITLE: Modified plant viruses as vectors

ABPR:
The invention relates to assembled particles of a plant virus containing a predetermined foreign peptide as part of the coat protein of the virus, and a method for their production. The foreign peptide is preferably a biologically functional peptide, the biological application of which requires or is enhanced by presentation of the peptide in association with a larger molecule or particle.

BSPR:
This invention relates to the use of viruses as carriers (vectors) for the production or presentation of foreign peptides. More particularly, the invention relates to the genetic manipulation of viral nucleic acid by incorporation of foreign nucleic acid sequences which are expressed as peptides in the virus particle (virion). In this specification the term "foreign", as applied to a peptide or to the nucleic acid encoding therefor, signifies peptide or nucleic acid sequences which are not native to the plant virus used as a vector. Such sequences can be alternatively described as exogenous or heterologous sequences. The term "peptide" includes small peptides and polypeptides.

BSPR:
The present invention utilises plant viruses as vector systems for the expression of foreign nucleotide sequences ie nucleotide sequences (RNA or DNA) which are not present in plant viruses, as found in Nature, and which in consequence code for peptides not normally found in any naturally occurring plant virus.

BSPR:
The present invention comprises assembled particles of a plant virus containing a foreign peptide. The plant viruses of the present invention are therefore modified forms of the native viruses and for convenience will be referred to as modified viruses.

BSPR:
The foreign peptides which may be incorporated into plant viruses according to this invention may be of highly diverse types and are subject only to the limitation that the nature and size of the foreign peptide and the site at which it is placed in or on the virus particle do not interfere with the capacity of the modified virus to assemble when cultured in vitro or in vivo. In broad concept, modified viruses may be formed from any biologically useful peptides (usually polypeptides) the function of which requires a particular conformation for its activity. This may be achieved by association of the peptide with a larger molecule eg to improve its stability or mode of presentation in a particular biological system. Examples of such peptides are peptide hormones; enzymes; growth factors; antigens of protozoal, viral, bacterial, or fungal origin; antibodies including anti-idiotypic antibodies; immunoregulators and cytokines eg interferons and interleukins; receptors; adhesins; and parts or precursors of any of the foregoing types of peptide. The peptide preferably contains more than 5 amino acids.

BSPR:
To produce modified plant virus particles in accordance with this invention the plant viral nucleic acid is modified by introducing a nucleotide sequence coding for the foreign peptide eg an animal virus antigen at that part of the plant viral genome which codes for an exposed portion of the coat protein, infecting plants or plant cells with the modified viral nucleic acid, and harvesting assembled particles of the modified virus. This procedure is best carried out by direct manipulation of the DNA of the virus in the case of DNA viruses or by manipulation of a cDNA corresponding to the RNA of an RNA virus. In the case of an RNA virus, an RNA transcript of the modified DNA is usually prepared for inoculation of plant cells or preferably whole plants so as to achieve a multiplication stage prior to the harvesting of assembled particles of the modified virus. In the case of a DNA virus, the DNA itself is introduced into the plant. In this way, the foreign peptide is initially expressed as part of the capsid protein and is thereby produced as part of the whole virus particle. The peptide may thus be produced as a conjugate molecule intended for use as such. Alternatively, the genetic modification of the virus may be designed in order to permit release of the desired peptide by the application of appropriate agents which will effect cleavage from the virus particle.

CLPR:
1. Assembled particles of a plant virus containing a foreign peptide encoded by an exogenous nucleotide sequence as part of the coat protein of the virus, the particles having been assembled in whole plants or in plant cells, and wherein the coat protein of the virus has a .beta.-barrel structure and said virus is selected from the group consisting of Comoviruses, Tombusviruses, Sobemoviruses, and Nepoviruses, and the site of insertion of the foreign peptide is in a loop between individual strands of .beta. sheet.

CLPR:
8. Virus particles according to claim 1, in which the foreign peptide is inserted in the .beta.B-.beta.C loop of the plant virus.

DEPR:
PLRV is not mechanically transmissible. Spread of PLRV from infected plants to uninfected plants
can only be accomplished by aphids. This is the reason that insecticide application is currently
necessary for controlling this disease. Virus resistant potatoes will no longer require
insecticides to control aphids. Potato cultivars which are resistant to PLRV often display no or
reduced titers of PLRV and the virus is not as easily transmitted from these plants to other
plants by aphids. This characteristic is of commercial significance because it limits the
potential for virus epidemics in the field.

AB: The invention provides a method for imparting resistance in animals to viruses,
and in plants to viruses and viroids, that express double-stranded RNA-like structures
(dsRNAs). This method enables the binding of pathogenic dsRNAs during the infection process
by expression of dsRNA-binding protein in transgenic animal and plant hosts, thus
interrupting the infection cycle and inhibiting disease. The presence of a dsRNA-binding
protein in a transgenic host renders the transgenic host resistant to the phenotypic
symptoms of viral infection and/or decreased pathogen replication. Accordingly, the present
invention provides a genetically engineered animal and plant, stably transformed to express
a dsRNA-binding protein, such that the transgenic host displays resistance to virus and/or
viroid challenge.

AB: The invention relates to assembled particles of a plant virus containing a
foreign peptide insert in the coat protein of the virus. The site of the insert is free from
direct sequence repeats flanking the insert. The invention also relates to a method of
production of the particles and their use, in particular in vaccines.

L9: Entry 13 of 52 File: USPT Sep 28, 1999

DOCUMENT-IDENTIFIER: US 5958422 A
TITLE: Modified plant viruses as vectors of heterologous peptides

ABPR:
The invention relates to assembled particles of a plant virus containing a foreign peptide insert
in the coat protein of the virus. The site of the insert is free from direct sequence repeats
flanking the insert. The invention also relates to a method of production of the particles and
their use, in particular in vaccines.

BSPR:
This invention relates to the use of viruses as carriers (vectors) for the production or
presentation of foreign peptides. More particularly, the invention relates to the genetic
manipulation of viral nucleic acid by incorporation of foreign nucleic acid sequences which are
expressed as peptides in the virus particle (virion). In this specification the term "foreign",
as applied to a peptide or to the nucleic acid encoding therefor, signifies peptide or nucleic
acid sequences which are not native to the plant virus used as a vector. Such sequences can be
alternatively described as exogenous or heterologous sequences. The term "peptide" includes small
peptides and polypeptides.

BSPR:
Our patent application WO 92/18618 describes the utilization of plant viruses as vector systems
for the expression of foreign nucleotide sequences, ie nucleotide sequences (RNA or DNA) which
are not present in plant viruses, as found in Nature, and which in consequence code for peptides

not normally found in any naturally occurring plant virus. The invention described therein
comprises assembled particles of a plant virus containing a foreign peptide. The plant viruses of
the invention are therefore modified forms of the native viruses and for convenience will be
referred to as modified viruses.

BSPR:
The foreign peptides which may be incorporated into plant viruses according to our prior
application WO92/18618 may be of highly diverse types and are subject only to the limitation that
the nature and size of the foreign peptide and the site at which it is placed in or on the virus
particle do not interfere with the capacity of the modified virus to assemble when cultured in
vitro or in vivo. In broad concept, modified viruses may be formed from any biologically useful
peptides (usually polypeptides) the function of which requires a particular conformation for its
activity. This may be achieved by association of the peptide with a larger molecule eg to improve
its stability or mode of presentation in a particular biological system. Examples of such
peptides are peptide hormones; enzymes; growth factors; antigens of protozoal, viral, bacterial,
fungal or animal origin; antibodies including anti-idiotypic antibodies; immunoregulators and
cytokines, eg interferons and interleukins; receptors; adhesions; and parts of precursors of any
of the foregoing types of peptide. The peptide preferably contains more than 5 amino acids.

BSPR:
Firstly, the process used for modifying the plant viral nucleic acid by introducing a nucleotide
sequence coding for a foreign peptide should avoid the presence of direct sequence repeats
flanking the insert. In the context of the present invention a construct containing a direct
sequence repeat is one in which an identical oligonucleotide sequence is present on both sides of
the inserted nucleotide. Such constructs can be genetically unstable because recombination can
occur between the sequence repeats leading to loss of the foreign peptide coding sequence and
reversion to the wild type sequence. Secondly, where the foreign oligonucleotide sequence is
inserted into the plant virus genome as a substitution for part of the existing sequence, the
resultant modified viral coat protein may be missing in an amino acid sequence which is important
for virus replication, encapsidation and spread in the plant. This defect may be readily
determined and avoided. Thirdly, the heterologous sequence should not be inserted at a
sub-optimal site.

BSPR:
The present invention comprises assembled particles of a plant virus containing a foreign peptide
in which the corresponding foreign nucleic acid has been inserted into the plant virus genome in
the absence of direct sequence repeats flanking the insert and preferably as an addition to the
existing nucleic acid.

BSPR:
In a further aspect of the present invention, cDNA clones of CPMV RNAs M and B have been
constructed, in which the cDNA clone of the M RNA contains an inserted oligonucleotide sequence
encoding a foreign peptide, which make use of the cauliflower mosaic virus (CaMV) 35S promoter
sequence linked to the 5' ends of the viral cDNAs to generate infectious transcripts in the
plant. This technique overcomes some of the problems encountered with the use of transcripts
generated in vitro and is applicable to all plant RNA viruses.

DEPR:
Oligonucleotide sequences encoding various foreign peptides (see Table 1) were substituted for
the sequence between the Nhe1 and AatII sites of pCP2-AatII as described in Example 1. The
pCP2-AatII variants and pCP-1 were linearised and inoculated onto the primary leaves of cowpea
plants. In all cases infections developed and stable chimaeric virus particles expressing the
appropriate foreign peptide were recovered from plants.

CLPR:
1. Assembled particles of a plant virus containing a foreign peptide insert as an addition at a
non-terminal site in the coat protein of the virus, the site of the insert in the coat protein
corresponding to a site in the plant virus genome which is free from direct nucleotide sequence
repeats flanking the insert and wherein the coat protein of the virus has a .beta.-barrel
structure and the site of insertion of the foreign peptide is in a loop connecting .beta. sheets
of the plant virus, wherein the plant virus is a comovirus.

CLPR:
4. Virus particles according to claim 1, in which the foreign peptide is inserted in the
.beta.B-.beta.C loop of the plant virus.

CLPR:
6. Virus particles according to claim 1 or 5, in which the foreign peptide is incorporated in an
exposed surface of the coat protein of the plant virus.

CLPR:
22. A method of producing plant virus particles according to any of claims 1 or 5, which
comprises inserting a nucleotide sequence coding for a foreign peptide into the virus genome of
the plant viral nucleic acid which codes for the coat protein so as to modify the plant viral
nucleic acid in such a way as to avoid the production of direct sequence repeats flanking the
introduced sequence, infecting plants, plant tissue, plant cells, or protoplasts with the
modified viral nucleic acid, and harvesting assembled particles of said plant virus.

CLPR:
24. A method according to any of claims 22, in which the foreign nucleotide sequence is inserted
by selecting two different restriction enzyme sites in the plant viral nucleic acid; cutting the
plant viral nucleic acid using the corresponding restriction enzymes; and inserting into the cut
viral nucleic acid a pair of complementary oligonucleotides which encode the foreign peptide and
which terminate in ends compatible with the restriction enzyme cutting sites, and wherein in the
complementary oligonucleotides, the sequence encoding the foreign peptide is flanked by plant
virus-specific sequences so that the foreign nucleotide sequence is inserted as an addition to
the plant viral nucleic acid.

CLPR:
25. A method according to claim 22, applied to an RNA plant virus, which comprises introducing a
DNA sequence coding for the foreign peptide into a cDNA corresponding to the RNA of the plant
virus which codes for an exposed portion of its coat protein, producing from the thus modified
cDNA an RNA transcript thereof, inoculating plants, plant tissue, plant cells, or protoplasts
with the transcript, optionally together with any other RNA required for

multiplication and
assembly of whole virus particles in the plant material, and harvesting assembled particles of
the modified virus.

CLPR:
26. A method according to claim 25, in which the modified cDNA is produced by introducing the DNA
encoding the foreign peptide into a DNA fragment excised from the plant viral cDNA, and
recombining the modified fragment so as to reconstitute the plant viral cDNA in modified form.

AB: The present invention relates to a method of preparation of transgenic plants
resistant to viral infections by introducing into the genoma of a host plant an antisense
gene construct constituted by: the domain F of the subgenomic promoter of a viral RNA; a
leader sequence of a viral ORF, downstream from said subgenomic promoter; the gene encoding
a viral coat protein, downstream from said leader sequence; and the 3'-terminal region of a
viral RNA, downstream from said gene. The present invention also relates to a recombinant
vector comprising a promoter functional in a host plant, and, operably linked to this
promoter, the antisense gene construct of the present invention.

L9: Entry 14 of 52
File: USPT
Sep 28, 1999

DOCUMENT-IDENTIFIER: US 5959181 A
TITLE: Method of preparation of transgenic plants resistant to viral infections and so obtained
plants

BSPR:
Recently, it was demonstrated for different viral species with tripartite or monopartite RNA,
that, through the introduction into plants of RNA-4 gene encoding the coat protein, transgenic
plants can be obtained which display a strong decrease in disease symptoms when they are exposed
to infections with the same virus.

BSPR:
Another strategy used in order to obtain transgenic plants resistant to determined viruses
consists in inserting into the plant a DNA sequence which is complementary to a portion of the
viral genome in antisense orientation (not encoding). Unfortunately, the use of such a strategy
gave unsatisfactory results. In fact, transgenic tobacco plants, obtained by using the antisense
gene of the coat protein of CMV and PVX, displayed a tolerance to virus only when they were
infected with low inoculum concentrations (Cuozzo et al., Biotechnol., 6:549-557, (1988);
Hemenway et al., EMBO J. 7:1273-1280, 1988). Furthermore, discouraging results were obtained when
antisense genes were used which were capable of complementing with different domains of genomic
RNAs of CMV. In fact, only in one case low resistance levels were observed (Rezaian et al., Plant
Molecular Biology, 11:463-471, 1988).

BSPR:
It has now been found that the drawbacks displayed by the prior art, as discussed hereinabove,
can be overcome by means of the method according to the present invention, which is based on the
use of an antisense gene construct which allows transgenic plants to be obtained which display a
complete resistance to virus, in absence of production of coat protein.

DOCUMENT-IDENTIFIER: US 5955647 A
TITLE: Method for using tobacco mosaic virus to overproduce peptides and proteins

BSPR:
A method is provided for overexpression in plants of heterologous peptides of from about 5 to 20
amino acids as fusion proteins inserted near, but preferably not at the carboxy terminus of the
coat protein of tobacco mosaic virus using a modified cDNA infectious clone of TMV. Despite
insertion of the foreign peptide sequence into the viral coat protein, stable virions are
provided by this invention so that systemic infections is readily achieved in suitable plants. In
some instances, the method utilizes coinfection of the plant with 1) the infectious clone having
a modified CP gene, but a wild type movement protein (MP) gene and 2) a second TMV infectious
clone having a wild type coat protein gene and a MP gene that has been modified to render the
movement protein dysfunctional.

AB: The present invention provides a method for enhancing the expression of genes in
plants by supplying a virally encoded booster sequence comprising the 5' proximal region of
the potyvirus genome to the plant. The booster sequence enhances the expression of foreign
genes or endogenous plant genes in plants by employing any known methodology of expressing
introduced genes in plants. The booster sequence may be used to enhance expression of any
gene, including foreign genes or endogenous plant genes, introduced by means of stable
transformation into the genome of the plant or introduced by expression from a plant viral
expression vector.

L9: Entry 16 of 52

File: USPT

Aug 17, 1999

DOCUMENT-IDENTIFIER: US 5939541 A
TITLE: Method for enhancing expression of a foreign or endogenous gene product in plants

DEPR:
The present Example sets forth an exemplary method for enhancing expression of an endogenous
plant gene or a foreign gene (or a portion of a foreign or endogenous gene) that has been
introduced to a plant as a fusion to a viral protein expressed from a viral vector. A viral
vector expressing a foreign gene or an endogenous plant sequence as a fusion to the coat protein
of the virus, such as the vector described in Sugiyama, Hamamoto, Takemoto, Watanabe, Okada,
"Systematic Production of Foreign Peptides on the Particle Surface of Tobacco Mosaic Virus," 359
FEBS Lett., 247 250 (1995), is one such example. The viral vector may be used to infect a
transgenic plant host that supplies the booster sequence via expression from stably incorporated
DNA copies of said booster sequence, for example the U-6B transgenic tobacco plants described
herein. The expression of the foreign peptides fused to the viral coat protein would be enhanced.

TITLE: TXU-5/B53-PAP antiviral biotherapeutic agent for the treatment of AIDS

DEPR:
Pokeweed antiviral protein (PAP) is an antiviral agent isolated from the leaves or seeds of
Phytolacca americana (Irvin and Uckun, Pharmacology and Therapeutics 55: 279, 1992). PAP displays
broad-spectrum antiviral activity against plant viruses, herpes simplex virus, cytomegalovirus,
poliovirus, and influenza virus. Aron et al., Agents Chemotherapy, 17, 1032 (1980). In fact,
pokeweed antiviral protein was discovered due to its ability to inhibit the transmission of
tobacco mosaic virus (TMV) in plants and it was subsequently demonstrated that the purified
protein was equally effective against a number of other plant viruses. Tomlinson et al., J. Gen.
Virol., 22, 225 (1974).

AB: A nucleotide sequence comprising a transcriptional regulatory sequence and a
sequence contiguous therewith and under the transcriptional control thereof, which
contiguous sequence encodes an RNA which consists of a plurality of sub-sequences,
characterized in that at least two of the sub-sequences have the sequences of viral RNAs and
the RNA contains at least one translational stop codon located upstream of the 3' terminal
sub-sequence. It is preferred that at least one of the sub-sequences is in an anti-sense
configuration with respect to virus RNA, and that the contiguous sequence encodes mRNA. The
invention also includes, inter alia, the use of such a sequence in the generation of virus
resistant or tolerant plants, and such plants comprising the sequence.

L9: Entry 18 of 52
File: USPT
May 25, 1999

DOCUMENT-IDENTIFIER: US 5907084 A
TITLE: Virus resistant or tolerant cells

BSPR:
Numerous attempts have been made to engineer viral resistance into plants by inserting
DNA-containing vectors into acceptor plant tissue, which DNA is capable of encoding viral
proteins in the thus transformed plant. The viral protein may confer resistance to an invading
virus comprising a viral protein substantially the same as that encoded by the introduced DNA.
Other attempts at engineering virus resistance in plants use anti-sense RNA which relies on the
introduction of DNA encoding an RNA strand which is complementary to the RNA of an invading virus
and thus interferes with the replication thereof. Plants displaying a broad degree of reduced
susceptibility, i.e. to more than one viral type, or a greater degree of reduced susceptibility
to a particular virus type, are highly desirable.

DEPR:
(1). Multigene DNA constructs comprising at least one non-structural gene wherein the multigene
DNA is under the control of a single set of genetic regulatory elements. By "non-structural gene"
is meant a gene capable of coding for a viral RNA molecule which is substantially incapable of
encoding for a viral polypeptide or protein but which is nevertheless capable of conferring an
RNA mediated reduced susceptibility of a plant virus in plant cells. (2). Constructs according to
clause 1, wherein the at least one non-structural gene is a viral gene. (3). Multigene DNA
constructs comprising at least one non-structural gene wherein the multigene DNA constructs are
capable of giving rise to viral elements in plant cells which are capable of conferring a reduced
susceptibility to plant viruses in plant cells, and wherein the multigene DNA is under the
control of a single set of genetic regulatory elements. (4) Constructs according to clauses 2 to
3 comprising at least one viral non-structural gene and one viral structural gene. (5) Constructs
according to any one of clauses 2 to 4 comprising at least two non-structural genes and no viral
structural gene elements. (6). Constructs according to clause 5 comprising from 2 to 5 viral
non-structural genes. (7). Constructs according to any one of clauses 1 to 3

comprising DNA
capable of coding for viral RNA molecules of tospoviruses, potyviruses, potexviruses,
tobamoviruses, luteoviruses, cucumoviruses, bromoviruses, closteroviruses, tombusviruses, and
furoviruses. (8) Constructs according to clause 7, wherein the DNA codes for non-structural viral
RNA molecules of nucleocapsid proteins, viral coat proteins, and non-structural viral proteins.
(9). Plants comprising multigene DNA constructs of any one of clauses 1 to 3. (10). Plants
according to clause 9 selected from the group comprising tomatoes, peppers, melons, lettuces,
caulifowers, broccolis, cabbages, brussels sprouts, sugar beet, corn (maize), sweetcorn, onions,
carrots, leeks, cucumbers, tobacco's alfalfa's, aubergines, beets, broad beans, celery's,
chicory's, cow peas, endives, gourds, groundnuts, papayas, peas, peanuts, pineapples, potatoes,
safflowers, snap beans, soybeans, spinaches, squashes, sunflowers, water-melons, and sorghums.
(11). Plants according to clause 9 selected from the group ornamentals consisting essentially of
Impatiens, IBegonias, Petumias, Pelargoniums (geraniums), Violas, Cyclamens, Verbenas, Vincas,
Tagetes, Primulas, Saint Paulia's Ageratums, Amaranthuses, Anthirrhinums, Aquilegias,
Chrysanthemums, Cineraria, Clovers, Cosmos's, Cowpeas, Dahlia's, Daturas, Delphiniums, Gerbera's,
Gladioluses, Gloxinias, Hippeastrums, Mesembryanthemums, Salpiglossis, and Zinnias. (12). A
method for obtaining plants displaying a reduced susceptibility to viruses which comprises: (a)
inserting into the genome of a plant cell a DNA construct according to any one of clauses 1 to 8;
(b) obtaining transformed cells; and (c) regenerating from the transformed cells genetically
transformed plants.

AB: The invention relates to assembled particles of a plant virus containing a
predetermined foreign peptide as part of the coat protein of the virus, and a method for
their production. The foreign peptide is preferably a biologically functional peptide, the
biological application of which requires or is enhanced by presentation of the peptide in
association with a larger molecule or particle.

L9: Entry 19 of 52 File: USPT Feb 23, 1999

DOCUMENT-IDENTIFIER: US 5874087 A
TITLE: Modified plant viruses as vectors

ABPL:
The invention relates to assembled particles of a plant virus containing a predetermined foreign
peptide as part of the coat protein of the virus, and a method for their production. The foreign
peptide is preferably a biologically functional peptide, the biological application of which
requires or is enhanced by presentation of the peptide in association with a larger molecule or
particle.

BSPR:
This invention relates to the use of viruses as carriers (vectors) for the production or
presentation of foreign peptides. More particularly, the invention relates to the genetic
manipulation of viral nucleic acid by incorporation of foreign nucleic acid sequences which are
expressed as peptides in the virus particle (virion). In this specification the term "foreign",
as applied to a peptide or to the nucleic acid encoding therefor, signifies peptide or nucleic
acid sequences which are not native to the plant virus used as a vector. Such sequences can be
alternatively described as exogenous or heterologous sequences. The term "peptide" includes small
peptides and polypeptides.

BSPR:
The present invention utilises plant viruses as vector systems for the expression of foreign
nucleotide sequences ie nucleotide sequences (RNA or DNA) which are not present in plant viruses,
as found in Nature, and which in consequence code for peptides not normally found in any
naturally occurring plant virus.

BSPR:
The present invention comprises assembled particles of a plant virus containing a foreign
peptide. The plant viruses of the present invention are therefore modified forms of the native
viruses and for convenience will be referred to as modified viruses.

BSPR:
The foreign peptides which may be incorporated into plant viruses according to this invention may
be of highly diverse types and are subject only to the limitation that the nature and size of the
foreign peptide and the site at which it is placed in or on the virus particle do not interfere
with the capacity of the modified virus to assemble when cultured in vitro or in vivo. In broad
concept, modified viruses may be formed from any biologically useful peptides (usually
polypeptides) the function of which requires a particular conformation for its activity. This may

be achieved by association of the peptide with a larger molecule eg to improve its stability or
mode of presentation in a particular biological system. Examples of such peptides are peptide
hormones; enzymes; growth factors; antigens of protozoal, viral, bacterial, or fungal origin;
antibodies including anti-idiotypic antibodies; immunoregulators and cytokines eg interferons and
interleukins; receptors; adhesins; and parts or precursors of any of the foregoing types of
peptide. The peptide preferably contains more than 5 amino acids.

BSPR:
To produce modified plant virus particles in accordance with this invention the plant viral
nucleic acid is modified by introducing a nucleotide sequence coding for the foreign peptide eg
an animal virus antigen at that part of the plant viral genome which codes for an exposed portion
of the coat protein, infecting plants or plant cells with the modified viral nucleic acid, and
harvesting assembled particles of the modified virus. This procedure is best carried out by
direct manipulation of the DNA of the virus in the case of DNA viruses or by manipulation of a
cDNA corresponding to the RNA of an RNA virus. In the case of an RNA virus, an RNA transcript of
the modified DNA is usually prepared for inoculation of plant cells or preferably whole plants so
as to achieve a multiplication stage prior to the harvesting of assembled particles of the
modified virus. In the case of a DNA virus, the DNA itself is introduced into the plant. In this
way, the foreign peptide is initially expressed as part of the capsid protein and is thereby
produced as part of the whole virus particle. The peptide may thus be produced as a conjugate
molecule intended for use as such. Alternatively, the genetic modification of the virus may be
designed in order to permit release of the desired peptide by the application of appropriate
agents which will effect cleavage from the virus particle.

CLPR:
3. A method according to claim 1, which comprises (a) introducing a DNA sequence coding for the
foreign peptide into a cDNA corresponding to the plant virus RNA which codes for an exposed
portion of the plant virus coat protein, (b) producing from the thus modified cDNA an RNA
transcript thereof, (c) inoculating a member of the group consisting of plants, plant tissue,
plant cells, and protoplasts with the transcript, if necessary together with any other RNA
required for multiplication and assembly of whole virus particles in the plant material, and (d)
harvesting assembled particles of the virus.

CLPR:
6. A method according to claim 1, which comprises (a) introducing a DNA sequence coding for the
foreign peptide into a cDNA corresponding to the plant virus RNA which codes for an exposed
portion of the plant virus coat protein; (b) inoculating a member of the group consisting of
plants, plant tissue, plant cells, and protoplasts with the thus modified cDNA, if necessary
together with any other RNA required for multiplication and assembly of whole virus particles in
the plant material; and (c) harvesting assembled particles of the virus.

TITLE: Health supplements containing phyto-oestrogens, analogues or metabolites thereof

BSPR:
There are 3 principal classes of phyto-oestrogens, viz. isoflavones, lignans, and coumestans. The
isoflavones are thought to have a broad range of biological functions in plants, although these
are poorly understood. However, two particular functions are recognised--(a) as phyto-alexin or
stressor chemicals which are secreted by the plant in response to attack by parasites such as
insects, fungi, viruses, etc. and which display activity against these parasites, and (b)
chemicals which encourage colonisation of nitrogen-fixing bacteria on the roots of legumes. The

biological functions in plants of the lignans and coumestans is not generally understood.

TITLE: Plant promoter

BSPR:
Even though providing constitutive expression of a gene in plants is often desirable, it is also
desirable in some instances to direct expression of a gene to particular tissues in a plant. Some
tissue specific plant promoters are known, such as those capable of directing expression
preferentially in the fruit of a plant, but the genome length transcript, i.e. full length
transcript or major transcript, promoters that have been obtained from double-stranded DNA plant
viruses all display strong, constitutive expression patterns. Extensive structure analysis of the
CaMV35S promoter sequence has identified domains within the viral promoter sequence that confer
tissue specificity (Odell et al. 1985; Benfey et al. 1989; Fang et al. 1989), but the promoter
sequence in its entirety is a constitutive promoter.

AB: This invention discloses transgenic plants, such as transgenic tobacco and
potato, having resistance to multiple viral taxonomic groups using parts of the 2,5A
oligoadenylate pathway. In particular, said plants are genetically engineered to contain a
DNA sequence encoding at least one polypeptide having a 2,5A synthetase activity. By this
means a step in the 2,5A oligoadenylate pathway heretofore believed to be missing in all
plants is provided so that viral infection in the transgenic plants is inhibited via a 2,5A
dependent endonuclease. Moreover, this invention relates to a process for the production of
said transgenic plants by transfection with a genetically engineered DNA sequence encoding
at least one polypeptide having a 2,5A synthetase activity.

L9: Entry 24 of 52
File: USPT
Dec 31, 1996

DOCUMENT-IDENTIFIER: US 5589625 A
TITLE: Transgenic plants displaying multiple virus resistance and a process for their production

BSPR:
In summary, the prior art does not permit the conclusion that the 2,5A oligoadenylate pathway can
be used as a basis for constructing transgenic plants displaying multiple virus resistance. Thus,
the technical problem of the present invention is to provide a transgenic plant displaying
resistance to multiple virus taxonomic groups using parts of the 2,5A oligoadenylate pathway.

BSPR:
One object of the present invention relates to a transgenic plant displaying multiple virus
resistance which contains a genetically engineered DNA sequence encoding at least one polypeptide
having a 2,5A synthetase activity, wherein said polypeptide upon expression is capable of
activating an endonuclease causing degradation of viral RNA.

BSPR:
In the present invention a transgenic plant is provided that displays resistance to multiple
viral taxonomic groups. The transgenic plant contains a genetically engineered DNA sequence
encoding at least one polypeptide having a 2,5A synthetase activity, wherein the polypeptide
activates an endonuclease contained within the plant, thereby causing degradation of viral RNA so
as to prevent or lessen infection. The invention also discloses propagating material derived from
such transgenic plants.

DEPR:
This invention provides a method for obtaining transgenic plants displaying resistance to
multiple viral taxonomic groups by restoring to said plants a functioning 2,5A oligoadenylate
pathway. In particular, plants containing parts of the 2,5A oligoadenylate pathway are
genetically engineered to contain a DNA sequence encoding at least one polypeptide having a 2,5A
synthetase activity. By this means a step in the 2,5A oligoadenylate pathway heretofore believed
to be missing in all plants is provided, so that viral infection in the transgenic plants is
inhibited via a 2,5A dependent endonuclease. Moreover, this invention relates to a process for
the production of said transgenic plants by transfection with a genetically engineered DNA
sequence encoding at least one polypeptide having a 2,5A synthetase activity.

DEPR:
A further object of the present invention is a propagating material derived from a transgenic
plant displaying resistance to multiple viral taxonomic groups.

DEPR:
A further object of the present invention is a process for the production of a transgenic plant
displaying resistance to multiple viral taxonomic virus groups comprising the introduction of a
genetically engineered DNA sequence encoding at least one polypeptide having a 2,5A synthetase
activity, into the genetic material of a suitable plant.

DEPR:
A further object of the present invention is the use of a genetically engineered DNA sequence
encoding at least one polypeptide having a 2,5A synthetase activity, for the production of a
transgenic plant displaying resistance to multiple viral taxonomic groups.

CLPR:
1. A transgenic plant that utilizes the 2,5A oligoadenylate pathway and displays resistance to
multiple plant viral taxonomic groups comprising a genetically engineered DNA sequence encoding
at least one polypeptide having a 2,5A synthetase activity, wherein said polypeptide activates an
endonuclease causing degradation of viral RNA.

CLPR:
17. A transgenic plant cell that utilizes the 2,5A oligoadenylate pathway and displays resistance
to multiple plant virus taxonomic groups comprising a genetically engineered DNA sequence
encoding at least one polypeptide having a 2,5A synthetase activity.

CLPR:
23. A plant cell displaying resistance to multiple plant virus taxonomic groups descended from
the plant cell of claim 17 and comprising said 2,5A synthetase activity.

ORPL:
Truve, et al., Principles and background for the construction of transgenic plants displaying
multiple virus resistance, Arch Virol (1994) [Suppl] 9:41-50.

AB: A method of suppressing virus gene expression in plants using untranslatable plus
sense RNA is disclosed. The method is useful for the production of plants that are resistant
to virus infection.

L9: Entry 25 of 52 File: USPT Dec 10, 1996

DOCUMENT-IDENTIFIER: US 5583021 A
TITLE: Production of virus resistant plants

DEPR:
All transgenic plant lines tested displayed wild-type sensitivities to PVY and to cucumber mosaic
virus. Typical necrotic local lesions formed when the 2RC lines were inoculated with tobacco
mosaic virus (data not shown).

DEPR:
While not wishing to be bound by speculation, it is suggested that the highly resistant and
recovery phenotypes of the 2RC lines can be accommodated by the following working model. This
model suggests the existence of an inducible, cytoplasmic-based, cellular activity that degrades
specific RNA sequences. In transgenic plants displaying the recovery phenotype, this RNA
degradation system is activated only after virus infection and by the additive level of transgene
RNA and viral RNA present. In contrast, the highly resistant lines may

have the activity fully
induced by the transgene transcript. The failure of a rootstock from a highly resistant line to
induce a scion from a susceptible line in grafting studies suggests the activity is a programmed
cell response not induced via a diffusible signaling molecule as is the case with systemically
acquired resistance (Kuc 1982; Ward et al., 1991). Once the antiviral system is activated, it is
absolute in its efficacy against TEV, yet it is not effective against the closely related virus
PVY.

DEPR:
The engineered resistance was TEV specific. None of the lines tested displayed any resistance to
PVY or tomato spotted wilt virus (TSWV) as a limited number of plants were naturally infected
with these viruses in the plot over the 2 year study.

DEPV:
Susceptible plant: A plant that supports viral replication and displays virus-induced symptoms.

AB: An isolated DNA sequence which codes for a PLRV replicase gene is disclosed
herein. A method for providing resistance to infection by a virus by expressing a replicase
gene in plants is also disclosed, as are transgenic potato plants and tubers containing the
replicase gene.

L9: Entry 26 of 52
File: USPT
Apr 23, 1996

DOCUMENT-IDENTIFIER: US 5510253 A
TITLE: Plants resistant to infection by PLRV

DEPR:
PLRV is not mechanically transmissible. Spread of PLRV from infected plants to uninfected plants
can only be accomplished by aphids. This is the reason that insecticide application is currently
necessary for controlling this disease. Virus resistant potatoes will no longer require
insecticides to control aphids. Potato cultivars which are resistant to PLRV often display no or
reduced titers of PLRV and the virus is not as easily transmitted from these plants to other
plants by aphids. This characteristic is of commercial significance because it limits the
potential for virus epidemics in the field.

TITLE: Virus-resistant plants

DEPR:
Accordingly, the present invention provides a method for genetically engineering plants by
insertion into the plant genome a DNA construct containing, inter alia, a small portion of the
viral genome of PVX and PVY such that the engineered plants display resistance to the plant
virus.

DOCUMENT-IDENTIFIER: JP 05328977 A
TITLE: PLANT VIRUS VECTOR AND PLASMID AND METHOD FOR ALLOWING TO EXPRESS FOREIGN GENE IN PLANT

FPAR:
CONSTITUTION: A plant virus vector is characterized in that a foreign gene is connected to the downstream of an exodermis protein gene of a plant virus through a base sequence inducing a read-through. The exodermis protein virus is preferably the gene of tobamo virus, etc. Examples of the foreign gene includes a peptide gene having pharmacological and physiological activities, a protein gene giving stress resistance and resistance against diseases and pests to plants, and a protein gene for changing the shapes and flower colors of plants. When the virus is RNA, the plant virus vector is obtained by inserting the cDNA of a plant RNA virus into the downstream of a promoter of a plasmid having the promoter for transcription in vitro, inserting a foreign gene into the downstream of the exodermis protein gene originated from the plant virus through a base sequence inducing a read-through, and subsequently producing the RNA by a transcription reaction in vitro.

DOCUMENT-IDENTIFIER: WO 9911806 A1
TITLE: PATHOGEN-RESISTANT TRANSGENIC PLANTS AND METHODS OF MAKING

FPAR:
The present invention provides pathogen-resistant transgenic plants and methods of making the plants. The transgenic plants display enhanced resistance to a variety of fungal, bacterial and viral plant pathogens due to expression of a gene that increases the unsaturated fatty acid content of the plant's cells, as compared with an equivalent, but non-transformed plant. The preferred embodiment of the invention is a plant expressing a heterologous DELTA -9 desaturase gene from yeast, which particularly increases cytosolic quantities of 16:1, 16:2 and 18:1 fatty acids.

FPAR:
Disclosed are nucleic acid constructs comprising a sequence encoding a plant viral coat protein
(e.g. the S-peptide of CPMV) containing a foreign or heterologous peptide insert (e.g. an epitope
for vaccine use) wherein the said coat protein has been modified such as to reduce its ability to
effect nucleic acid packaging within viral particles. The modification is preferably at the
C-terminus. Also disclosed are corresponding nucleic acid preparations, plus methods, processes
and other materials (e.g. plants, virus particles, and compositions) based on the nucleic acids.

File: EPAB

Dec 19, 1996

DOCUMENT-IDENTIFIER: WO 9640948 A2
TITLE: RESISTANCE TO VIRUSES AND VIROIDS IN TRANSGENIC PLANT AND ANIMAL HOSTS EXPRESSING dsRNA-BINDING PROTEIN

FPAR:
The invention provides a method for imparting resistance in animals to viruses, and in plants to viruses and viroids, that express double-stranded RNA-like structures (dsRNAs). This method enables the binding of pathogenic dsRNAs during the infection process by expression of dsRNA-binding protein in transgenic animal and plant hosts, thus interrupting the infection cycle and inhibiting disease. The presence of a dsRNA-binding protein in a transgenic host renders the transgenic host resistant to the phenotypic symptoms of viral infection and/or decreased pathogen replication. Accordingly, the present invention provides a genetically engineered animal and plant, stably transformed to express a dsRNA-binding protein, such that the transgenic host displays resistance to virus and/or viroid challenge.

TITLE: PRODUCTION OF PEPTIDES IN PLANTS AS VIRAL COAT PROTEIN FUSIONS

FPAR:
The present invention relates to foreign peptide sequences fused to recombinant plant viral structural proteins and a method of their production. Fusion proteins are economically synthesized in plants at high levels by biologically contained tobamoviruses. The fusion proteins of the invention have many uses. Such uses include use as antigens for inducing the production of antibodies having desired binding properties, e.g., protective antibodies, or for use as vaccine antigens for the induction of protective immunity, including immunity against parasitic infections.

TITLE: PLANT VIRUS-RESISTANT TRANSGENIC PLANTS AND METHOD FOR PRODUCING SAME

FPAR:
A potyvirus-resistant plant having in its genome one or more DNA fragments expressing transcripts
corresponding to a protein or protein fraction of a donor virus, e.g. a protein involved in the
formation of a potyvirus replication complex, a protein involved in the transport of a potyvirus
between cells, or a protein having a similarity with the cleavage sites of potyvirus viral
proteins. A method for producing plant virus-resistant plants comprises inserting vectors from a
donor virus complementary cDNA libray into cells or tissue fragments from said plants, and
selecting plants displaying plant virus resistance.

DERWENT-WEEK: 200111

TITLE: New tagged phosphoramidites and phosphonates for labelling nucleic acid - contain group
detectable by mass spectrometry, used to detect or quantify polymorphisms or specific RNA, e.g.
for genotyping and detecting mutations

ABTX:
USE - Probes and primers derived from (I), i.e. where X is replaced by a nucleic acid sequence,
are used as tags for use in any nucleic acid reaction that requires separation of molecules
according to size. Typical of many applications are in polymerase chain reactions, differential
display, RNA or dideoxy fingerprinting, ligase or nuclease-based assays etc., e.g. in diagnosis
(detecting mutations), forensic studies, detecting polymorphisms, genetic mapping (genotyping of
animals, plants, bacteria, viruses and fungi), in toxicology, animal breeding, analysis of gene
expression and sequencing by hybridisation.

TITLE: New nucleic acid constructs encoding a modified plant viral protein - useful for provoking
an immune response in a mammal

ABTX:
Also claimed are: (1) a nucleic acid composition (I) containing sequences which encode other
components required for assembly and/or replication of viral particles. The peptide insert is
displayed on their surface; (2) a host cell containing (I), preferably a cow pea plant cell; (3)
a part of a plant containing modified viral particles; and (4) A population of modified plant
virus particles.

TITLE: New modified peptide(s) - obtained by substitution with an amino acid which is modifiable
by a reaction and replacing other amino acids which are not to be modified

ABTX:
USE - The methods can be used for the modification of biologically active peptides such as
hormones, drugs, toxins and peptides which act on lipid bilayer membranes. The modified peptides
can be used e.g. in the body of an animal or plant or parts in order to affect the structure or
integrity or permeability of a foreign body such as a microorganism, parasite or virus present in
the body of the animal or plant or within the cells of the body of the animal or plant. They can
also be used in assays, purifications or sensors.

TITLE: Plant virus assembled particles contg. foreign peptide insert - useful in vaccines, esp.
for protecting animals, including humans, from virus infections

ABTX:
Assembled particles of a plant virus, contg. a foreign peptide insert (A) in the coat protein
region, are new. The site of the insert is free of direct sequence repeats flanking the insert,
and the virus is pref. Cowpea Mosaic Virus (CPMV). Also claimed are: (1) a fragment of CPMV coat
protein cDNA, contg. DNA encoding (A) or a site corresp. to an exposed surface of a coat protein,
free from direct repeats flanking the insert; (2) a vector contg. the fragment of (1) which is
esp. a full-length cDNA of CPMV M RNA contg. the foreign DNA insert; and (3) an RNA transcript of
(1) or (2), which is pref. capped.

ABEQ:

DERWENT-WEEK: 200136

TITLE: Transgenic plants with multiple virus resistance - genetically engineered using DNA encoding 2,5A synthetase

AB TX:
A transgenic plant (I) displaying multiple virus resistance contains a genetically engineered DNA sequence encoding at least one polypeptide with 2,SA synthetase activity. The polypeptide is capable of activating an endonuclease causing degradation of viral RNA.

ABEQ:
A transgenic plant (I) displaying multiple virus resistance contains a genetically engineered DNA sequence encoding at least one polypeptide with 2,SA synthetase activity. The polypeptide is capable of activating an endonuclease causing degradation of viral RNA.

ABEQ:
A transgenic plant that utilizes the 2,5A oligoadenylate pathway and displays resistance to multiple plant viral taxonomic groups comprising a genetically engineered DNA sequence encoding at least one polypeptide having a 2,5A synthetase activity, wherein said polypeptide activates an endonuclease causing degradation of viral RNA.
